

TERMINOLOGY DEFINITIONS AND INTERPRETIVE FRAMEWORK

Purpose of Terminology Definitions

The following terminology definitions are provided to clarify interpretation of terms used throughout this disclosure. These definitions are intended to broaden understanding rather than limit scope. Terms shall be interpreted in accordance with their functional meaning within longitudinal wearable physiologic monitoring systems.

Rigidity

The term 'rigidity' refers broadly to any measurable or inferred mechanical, structural, or functional stiffness condition of tissue or anatomy. Rigidity may be directly measured, indirectly inferred, computationally modeled, or derived through multi-modal sensing and does not require measurement of internal pressure or anatomical parameters.

Tumescence and Physiologic Activation

'Tumescence' or 'physiologic activation' refers to transitional biological states involving vascular, mechanical, neurologic, or thermal changes associated with erection development or recovery. The term encompasses partial, transitional, or stabilized states rather than binary conditions.

Longitudinal Monitoring

'Longitudinal monitoring' refers to repeated or continuous acquisition of physiologic data over time sufficient to enable trend analysis, baseline modeling, adaptation detection, or historical comparison.

Physiologic State

A 'physiologic state' represents a computationally interpreted biological condition derived from one or more sensing modalities. States may be categorical, probabilistic, continuous, or multi-dimensional representations of biological behavior.

Sensor Fusion

'Sensor fusion' refers to any method of combining multiple sensing inputs to generate a derived interpretation or composite metric. Fusion may include statistical, algorithmic, rule-based, or machine learning approaches.

Wearable Device

A 'wearable device' refers to any structure positioned on, near, or integrated with the body for purposes of physiologic monitoring, including rings, bands, garments, distributed sensors, or future bio-integrated implementations.

Abstract Representation

'Abstract representation' refers to presentation of physiologic information through indices, symbols, scores, graphical patterns, or non-explicit visual formats rather than direct anatomical visualization.

Compatibility or Comparative Physiology

'Compatibility' or 'comparative physiology' refers broadly to analytical comparison between physiologic datasets originating from one or more users, devices, or monitoring sessions. Compatibility does not require disclosure of explicit biological characteristics.

These definitions are illustrative and non-limiting. Additional terminology appearing in the disclosure shall be interpreted in a manner consistent with the broad conceptual framework of wearable longitudinal physiologic monitoring systems.
