

DETAILED DESCRIPTION OF THE INVENTION - CONTINUATION AND FUTURE EMBODIMENTS ANCHOR

The present disclosure is intended to serve as a foundational specification supporting future patent filings including continuations, continuations-in-part, divisionals, and related applications directed to any subset of the disclosed systems, devices, methods, software architectures, data representations, accessories, or multi-node implementations.

Accordingly, features described herein may be claimed independently, in combination, or in any technically feasible arrangement, including combinations not expressly illustrated, without departing from the scope of the inventive concepts. Elements described as part of one embodiment may be substituted into, integrated with, or applied to other embodiments where functionally appropriate.

The disclosure further contemplates future embodiments and improvements that may be developed after the filing date, including new sensing modalities, alternative materials, revised form factors, expanded computational frameworks, additional device nodes, new communication standards, and updated manufacturing processes, provided such embodiments perform substantially similar functional objectives within physiologic monitoring and analysis systems.

No particular naming convention, product branding, or commercial configuration is required for the disclosed inventions. The scope of the disclosure is defined by the functional and structural principles described herein and is not limited by any illustrative terminology used for convenience.

This specification is therefore intended to support broad claim scope across present and future implementations, including those later developed, refined, or optimized, and to preserve priority for subsequent filings derived from the disclosure.
