

MOTION VALIDATION, ANTI-SPOOFING, AND SESSION AUTHENTICITY EMBODIMENTS

In various embodiments, the intraluminal compliance and distance profiling device incorporates motion validation and anti-spoofing systems configured to ensure that measurement sessions correspond to authentic physiologic conditions rather than simulated or improper use environments.

The device may utilize inertial measurement units, accelerometers, gyroscopes, magnetometers, or orientation sensors to detect motion stability, insertion orientation, and characteristic movement signatures associated with valid measurement conditions.

In certain embodiments, session authenticity is evaluated using multi-factor validation combining motion stability, pressure response behavior, temperature readings, and distance sensing consistency. The computational system may generate a session validity score representing confidence that measurements were obtained under biologically relevant conditions.

Anti-spoofing embodiments may detect non-biologic usage scenarios such as in-air operation, placement against rigid surfaces, mechanical simulation, or artificial signal injection. Detection may rely on mismatched sensor correlations, absence of expected thermal signatures, abnormal compliance behavior, or inconsistent distance variability.

The system may further employ temporal analysis requiring measurements to satisfy stability thresholds over defined time intervals. Measurements obtained during excessive motion or rapid orientation change may be automatically rejected or flagged for correction.

In certain implementations, baseline enrollment sessions may establish individualized reference patterns describing typical motion, pressure, and temperature characteristics for a user. Future sessions may be compared against baseline signatures to improve authenticity assessment.

The computational platform may provide real-time guidance prompting stabilization, repositioning, or repetition when authenticity thresholds are not met. Guidance may be delivered through visual indicators, auditory feedback, or haptic notifications.

In some embodiments, validated sessions may be cryptographically tagged within the computational ecosystem, allowing downstream analytic systems to rely only on authenticated measurement data for modeling or compatibility analysis.

Anti-spoofing mechanisms may also support research integrity by preventing automated data fabrication or unauthorized batch data generation within distributed measurement networks.

Accordingly, motion validation and session authenticity embodiments enhance reliability of collected physiologic data, prevent misuse or manipulation of sensing systems, and ensure that derived analytic outputs are based upon verified measurement conditions.
