

DEFINITIONS AND TERMINOLOGY

DEFINITIONS AND TERMINOLOGY

For purposes of the present disclosure, the following terms are provided to clarify scope and are not intended to limit embodiments unless explicitly stated otherwise. “Intimate Physiology” refers broadly to physiological processes associated with sexual health, arousal regulation, reproductive function, relational synchronization, autonomic activation patterns, emotional engagement states, and contextual bodily responses occurring before, during, or after intimate interaction events. Intimate physiology may include systemic, localized, neurological, cardiovascular, thermal, endocrine, behavioral, or psychophysiological signals. “Contextual Physiology” refers to whole-body physiological signals that provide interpretive context for localized anatomical measurements. Contextual physiology includes but is not limited to autonomic nervous system activity, heart rate variability, respiratory patterns, thermoregulation, electrodermal response, movement state, environmental exposure, fatigue state, recovery status, and stress modulation. “Node” refers to any wearable, body-positioned, environmental, implantable, or remotely communicating sensing device configured to collect physiological or contextual data within a distributed biometric system architecture. “Node 5” refers specifically to a systemic context acquisition device configured to monitor full-body physiological signals relevant to interpretation of intimate physiological states. Node 5 may operate independently or in synchronization with one or more additional nodes configured to monitor localized anatomical regions. “Wearable Ring” includes any closed-loop, semi-closed, adjustable, elastic, rigid, or hybrid wearable structure positioned on a finger, toe, appendage, or anatomical region and capable of supporting sensing, communication, or computational functionality. “Chest Patch” includes adhesive, textile-integrated, magnetic, mechanical, strap-based, implant-adjacent, or conformal devices positioned on the thoracic region for acquisition of cardiac, respiratory, thermal, motion, or autonomic signals. “Physiological Context Model” refers to computational outputs derived from fused sensor inputs representing interpreted systemic bodily states rather than raw sensor values. Such models may include readiness indices, arousal context scores, synchronization curves, recovery metrics, compatibility parameters, or derived physiological classifications. “User” refers to an individual interacting with or monitored by the system and may include single-user, paired-user, or multi-user synchronized monitoring environments. “Machine Learning” includes supervised, unsupervised, reinforcement, adaptive, neural, statistical, probabilistic, or hybrid computational techniques configured to interpret, predict, classify, or personalize physiological data. Unless explicitly limited, all terminology herein shall be interpreted expansively to include future sensing modalities, unknown physiological markers, emerging wearable form factors, and later-developed computational methods capable of performing substantially similar functions.
